## Characteristic description

With the high performance and reliable quality, TM1925 is the nine-channel LED constant current driver control dedicated circuit, integrated with circuits such as MCU single-wire digital interface, data latch, LED constant current driver and PWM brightness control internally. As chip can be cascaded through the single-wire digital interface (DI, DO), peripheral control unit can control the chip and follow-up chip cascaded with it only with a single wire. The PWM brightness at TM1925 output port can also be set separately through peripheral control unit. VDD pin is internally integrated with a 5 V Zener diode with few peripheral devices. The product has excellent performance and reliable quality.

## Functional characteristics

$>$ CMOS technology is provided
$>$ The OUT output port can withstand 24 V voltage
$>5 \mathrm{~V}$ Zener diode is internally integrated in VDD, of which can support $6 \sim 24 \mathrm{~V}$ voltage after concatenating a resistance
$>$ The brightness regulation circuit can adjust 256 grades of brightness
$>$ Single-wire serial cascade interface
$>$ Vibration mode: RC vibration is integrated internally. Clock synchronization can be realized according to signals on data cable. Follow-up data can be automatically regenerated and transmitted to subordinate through data output terminal after receiving data of this unit. Signals don't distort or attenuate with cascade being further
$>$ Power-on reset circuit is integrated internally
$>$ Internal control mode (colorful flicker)
> PWM control terminal can realize 256 grades of regulation, with a scanning frequency of 7 KHz .
$>$ The reception and decoding of data can be completed through a signal line
$>$ At the refresh rate of 30 fps , cascade number is no less than 1024 bit and data transmission rate can be up to 800 Kbps
$>$ Transmission distance between any two points is no less than 30 m
> Package type: SOP14, DIP14

Equivalent circuit of output and input

Integrated circuit is SSD, which is easy to produce mass static in dry season or dry environment. As electrostatic charge may damage the integrated circuit, Titan Micro Electronics suggests taking all appropriate preventive measures for protecting integrated circuit. Improper operation and weld may damage the ESD or degrade its performance to make the chip unable to work normally.

Nine-channel LED Constant Current Driver TM1925
Limit parameters
(1) (2)

| Parameters |  |  | Scope | Unit |
| :---: | :---: | :---: | :---: | :---: |
| VDD | Voltage of logic power |  | $-0.4 \sim+7.0$ | V |
| Vin | Voltage scope of input terminal | DIN | $-0.4 \sim \mathrm{VDD}+0.7 \mathrm{~V}$ | V |
| Iout | Current of output terminal (DC) | OUTR, OUTG, OUTB | $19 \sim 21$ | mA |
| Vout | Voltage scope of output terminal | OUTR, OUTG, OUTB | $-0.4 \sim+30.0$ | V |
| Fosc | Rate of DIN clock | DIN | $400 \sim 900$ | KHz |
| Topr | Scope of Operating temperature |  | $-40 \sim+85$ | ${ }^{\circ} \mathrm{C}$ |
| Tstg | Scope of Storage temperature |  | $-55 \sim+150$ | ${ }^{\circ} \mathrm{C}$ |
| ESD | Human body mode (HBM) |  | 3000 | V |
|  | Machine mode (MM) |  | 200 | V |

(1) As operating chip at the grades in above table for long time may cause permanent damage to devices and lower the reliability of devices, we suggest never operating chip beyond these limit parameters under any other conditions;
(2) All voltage values are tested relatively to system.

## Range of recommended operating condition

## Time sequence characteristics

Diagram 4

## Function Description

With single-wire communication mode, this chip sends signals in the way of return to one code. After power-on reset, the chip receives $24 \times 3$ bit data from DIN terminal, and then DO port starts to forward the data continually sent from DIN terminal to provide input data for next cascade chip. Before forwarding data, DO port is under high level all the time. If DIN inputs RESET signal, the chip will receive $24 \times 3$ bit data and output corresponding PWM duty ratio after successful reset, and wait to receive new data again. After completely receiving the beginning $24 \times 3$ bit data, data are forwarded through DO port. Before receiving the RESET signal, the original output of OUTR, OUTG and OUTB pins remain unchanged.

As the chip is provided with automatic shaping forwarding technology, signals will not distort or attenuate so that cascade number is only limited by the requirements of screen renewing speed but not signal transmission.

## Data structure

PWM mode command:
If this data package is PWM setting data in 24 bit data package. Its structure is shown as follows:

The above is the PWM data format set for the first group of RGB. Setting a piece of TM1925 needs 3 groups of data packages with the same format.

PWM duty ratio is continuously adjustable from $0-256$. The $24 \times 3$ bit data are transmitted from high to low according to the sequence of RGB. Every 24 bits can be spitted into 3 data of 8 bit to be transmitted. The high level time between bytes shall be no more than the time of RESET signal, otherwise the chip will reset to receive data again, and data transmission cannot be realized.

## Communication rate

| $\begin{gathered} \text { Symbo } \\ \hline 1 \end{gathered}$ | Parameters | Test condition | $\underset{\mathbf{m}}{\overline{\text { Minimu }}}$ | Typical value | Maximu m | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| T0L | Input 0 code, low level time | $\begin{aligned} & \mathrm{VDD}=5 \mathrm{~V} \\ & \mathrm{GND}=0 \mathrm{~V} \end{aligned}$ | 150 | 300 | 450 | ns |
| T1L | Input 1 code, low level time |  | 600 | 750 | 900 | ns |
| T0L’ | Input 0 code, low level time |  | -- | 340 | -- | ns |
| T1L' | Input 1 code, low level time |  | -- | 680 | -- | ns |
| T | Cycle time of 0 code or 1 code |  | -- | 1200 | -- | ns |
| Treset | Reset code, high level time |  | 140 | 500 |  | $\mu \mathrm{s}$ |

Note: the cycle time of transmitting 0 code or 1 code is 1200 ns ( 800 KHz frequency).

## Data transmission and forward

Diagram 5
D1 is data transmitted by controller and D2, D3, D4 are data forwarded by cascade TM1925.

The process of chip cascade and data transmission and forwarding: Controller sends data (D1); when Chip 1 received the first 72 bit, it doesn't begin to forward data (D2). Then controller sends data continuously and Chip 1 receives the second 72 bit. Since Chip 1 has stored the First 72 bit, when Chip 1 forwarded the second 72 bit through DO and Chip 2 received data (D2) forwarded from Chip 1, Chip 2 doesn't begin to forward data (D3). Next, controller sends data continuously and Chip 1 forwards the third 72 bit to Chip 2. Since Chip 2 has stored a 72 bit, it will forward the third 72 bit (D3). After Chip 3 receives the third 72 bit, if controller sends a RESET high level signal at that time, all chips will reset and output the 72 bit data respectively received through three groups of RGB ports to complete a data refreshing cycle. Chips returns to reception readiness.

## Internal control mode

When chip power is normal and DIN is tested to be no input signal, or 600 ms after original normal signal missed, chips will enter internal control mode and flicker circularly as follows.
The flicker principle of internal control mode is as follows:

|  | RGB Status |  |  |
| :---: | :---: | :---: | :---: |
| Status No. | $\mathbf{R}$ | $\mathbf{G}$ | $\mathbf{B}$ |
| 0 | 0 | 0 | 0 |
| 1 | 1 | 0 | 0 |
| 2 | 0 | 1 | 0 |
| 3 | 1 | 1 | 0 |
| 4 | 0 | 0 | 1 |
| 5 | 1 | 0 | 1 |
| 6 | 0 | 1 | 1 |
| 7 | 1 | 1 | 1 |

Remarks: "0" means light off and "1" means light on.

## Application information

## 1. How to calculate data refreshing rate

Data refreshing time is calculated by the number of pixels cascade in a system. Usually, a group of RGB is a pixel (or a section). A TM1925 can control 3 groups of RGB.
Calculation is generally made according to normal mode:
The highest transmission rate of a BIT is $1,200 \mathrm{~ns}$ ( 800 KHz frequency). As a pixel data totally contains 24 Bits including red (8 BIT), green (8BIT), blue (8BIT), the transmission time is $24 \times 1.2 \mathrm{uS}=28.8 \mathrm{uS}$. Hence, if there are 2,000 pixels in a system in all, the time of once refreshing all display will be $28.8 \mathrm{uS} \times 2,000=57.6$ mS (neglecting the time of RESET code), i.e. the refresh rate in a second is: $1 \div 57.6 \times 1,000 \approx 17.36 \mathrm{~Hz}$.
The table of highest data refreshing rate corresponding with cascade points is shown as follows:

|  | Normal mode |  |
| :---: | :---: | :---: |
| Pixel | Time of fastest <br> refreshing data <br> $(\mathrm{mS})$ | Highest <br> refreshing rate <br> $(\mathbf{H z})$ |
| $1 \sim 500$ | 14.4 | 69 |
| $1 \sim 800$ | 23.04 | 44 |
| $1 \sim 1,000$ | 28.8 | 35 |
| $1 \sim 1,500$ | 43.2 | 23 |
| $1 \sim 1,800$ | 51.84 | 19 |
| $1 \sim 2,000$ | 57.6 | 17 |

If data refreshing rate is not required too much for system, there will be no requirement for the number of cascade pixel matrixes. Theoretically, TM1925 infinite cascades can be used only if power supply is in normal condition.

## 2. How to make TM1925 in best constant current condition

TM1925 output is constant current driver. According to the constant current curve of output, under 20 mA constant current, the voltage of OUT terminal entering into constant current area shall be more than 1.2 V to produce constant current on chip. However, this OUT terminal voltage is not the higher, the better. Since higher voltage leads to larger power consumption on chips, serious chip heating will reduce the reliability of whole system. Therefore, it is suggested to control the voltage Vout within 1.2~3 V when OUT terminal is on. Also, series resistance mode should be used commonly for operation. Theoretical calculation of resistance is shown as follows:

System driving voltage: VDD
Turn-on voltage drop of single LED: Vled
Number of LED in series: n
Constant current value: Iout
Voltage of constant current: 1.5 V
Resistance: R
R = (VDD-1.5-n×Vled)/ Iout

Nine-channel LED Constant Current Driver TM1925
For example: If the power supply of the system is 24 V , the turn-on voltage drop of single LED is 2 V , number of LED in series is six and constant current value is 20 mA , it can be calculated according to above formula that: $\mathrm{R}=(24-1.5-2 \times 6) / 0.02=525 \Omega$, i.e. only a resistance about $525 \Omega$ is required to cascaded on the pin of OUT.

## 3. How to expand current with TM1952

Each OUT terminal of TM1952 can only output 20 mA constant current at most. For any requirement of driving with larger constant current value, three OUT terminals can be shortly jointed for operation, as each short circuit of OUT can increase 20 mA constant current value and at most 60 mA constant current can be generated after three shortly circuits. The disadvantages of this method are software is required to cooperative with control and 3 register values shall be recorded while advantages are that the required current value can be obtained precisely and constant current is relatively large.

## 4. Power configuration

TM1925 can be configured to be 6~24 V voltage to supply power while different power resistances shall be configured according to different voltages. The calculation method of resistance is: since power voltage is reduced with the improvement of load in practical application, current flowing through VDD pin is calculated as 10 mA and therefore the resistance of VDD is $\mathrm{R}=(\mathrm{DC}-5.5 \mathrm{~V}) / 10 \mathrm{~mA}$ (DC is power voltage).

List of configured resistance value is shown as follows:

| Power voltage DC | Suggested resistance value between power interface and <br> VDD |
| :---: | :---: |
| 5 V | Resistance is not required and internal Zener diode doesn't <br> work. |
| 6 V | $50 \Omega$ |
| 9 V | $350 \Omega$ |
| 12 V | $650 \Omega$ |
| 24 V | $1.8 \mathrm{~K} \Omega$ |

## 5. Method of driving LED by program

5.1 Voltage of RGB ports shall be guaranteed to get chips entered into constant current to realize the control of chips to the brightness of LED (Refer to "Constant Current Curve" for details).
5.2 Power on and reset the chips. Port voltage reaches 1.2 V and constant current of RGB of output channel is 20 mA , so the allowable maximum current is 20 mA .
5.3 LED brightness can be adjusted arbitrarily by changing PWM value. If the PWM value is 0 , the output will be full and LED will be off. If the PWM value is set to FFH, the output will be maximum low-level duty ratio and LED will be on.

## Constant current curve

When apply TM1925 to LED panel design, electricity difference between channels will be very small, which derives from the excellent characteristics of TM1925:
$>$ Besides, the stability of output electricity will not be influenced when load terminal voltage changes, as is shown in Diagram 8.
$>$ Driving current on TM1925 port is constant current value.
